

INTERFERENCE

# Interferensi

Penjumlahan gelombang dengan frekuensi sama:

$$\psi_1 = E_1 \sin(kx - \omega t + \varepsilon_1) \quad \psi_2 = E_2 \sin(kx - \omega t + \varepsilon_2)$$

$$\alpha_1 = kx + \varepsilon_1 \quad \alpha_2 = kx + \varepsilon_2$$

$$\psi_1 = E_1 \sin(\alpha_1 - \omega t) \quad \psi_2 = E_2 \sin(\alpha_2 - \omega t)$$

$$\psi = \psi_1 + \psi_2 = E \sin(\alpha - \omega t) = E \sin(kx - \omega t + \varepsilon)$$

$$E^2 = E_1^2 + E_2^2 + 2E_1E_2 \cos(\alpha_2 - \alpha_1) \quad I = I_1 + I_2 + \underline{2\sqrt{I_1I_2} \cos(\alpha_2 - \alpha_1)}$$

## Tipe interferensi

Interferensi Konstruktif:  $I_{\max} = I_1 + I_2 + 2\sqrt{I_1I_2}$

Interferensi Destruktif:  $I_{\min} = I_1 + I_2 - 2\sqrt{I_1I_2}$

**Koheren:** beda fasa awal  $\varepsilon_2 - \varepsilon_1$  adalah konstan.

**Inkoheren:** beda fasa awal  $\varepsilon_2 - \varepsilon_1$  bervariasi secara random baik secara waktu/ruang

**Beda Fasa** untuk dua gelombang pada jarak  $x_1$  dan  $x_2$  dari sumber cahaya:

$$\delta = (kx_2 - \omega t + \varepsilon_2) - (kx_1 - \omega t + \varepsilon_1) = k(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1)$$

Dalam sebuah medium:

$$\delta = \frac{2\pi}{\lambda_m}(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1) = \frac{2\pi}{\lambda}n(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1)$$

**Beda Lintasan Optik/ Optical Path Difference (OPD):**  $n(x_2 - x_1)$

**Panjang Lintasan Optik/ Optical Path Length (OPL):**  $nt$

**Conditions for Interference:**

$$I = I_1 + I_2 + 2\sqrt{I_1 I_2} \cos(\alpha_2 - \alpha_1)$$

$$\delta = (kx_2 - \omega t + \varepsilon_2) - (kx_1 - \omega t + \varepsilon_1) = k(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1)$$

$$\delta = \frac{2\pi}{\lambda_m} (x_2 - x_1) + (\varepsilon_2 - \varepsilon_1) = \frac{2\pi}{\lambda} n(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1)$$

$$I = I_1 + I_2 + 2\sqrt{I_1 I_2} \cos \delta$$

(i)  $(\varepsilon_2 - \varepsilon_1)$  must remain constant with time. (ii)  $(x_2 - x_1)$  should not exceed the wave-train length.

**Visibility:** 
$$V = \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}} = \frac{2\sqrt{I_1 I_2}}{I_1 + I_2}$$

**Interferometer:**

An instrument designed to exploit the interference of light and the fringe patterns that result from optical path differences. An interferometer divides an initial beam into two or more parts that travel diverse optical paths and then reunite to produce an interference pattern. According to the manner in which the initial beam is separated, interferometers can be broadly classified as wavefront division interferometers (divide the same wavefront of a coherent beam of light) and amplitude division interferometers (divide the initial beam into two parts).

## Young's Double Slits:

The waves from  $S_0$  illuminate the slits  $S_1$  and  $S_2$  which act as coherent secondary sources. Each wavefront is split and since the phase difference is constant for waves arising from  $S_1$  and  $S_2$ .

$$OPD = n(S_1P - S_2P) \approx na \sin \theta = m\lambda$$

$$\sin \theta \approx \tan \theta = y/s$$

$$y_m = \frac{m\lambda s}{na} \quad \Delta y = \frac{\lambda s}{na} \quad \theta_m = \frac{y_m}{s} = \frac{m\lambda}{na}$$

**Example:**

The slits  $S_1$  and  $S_2$  in Young's experiment are 1 mm apart (center to center) and the screen placed such that  $s = 5$  m. If the incident light has a wavelength  $\lambda = 589.3$  nm and the system is in air,  $n = 1.00029$ , find the distance of the first bright fringe from the central bright fringe. If the system is immersed in water,  $n = 1.33$ , what will be the result?

$$(1): \quad m = 1; \quad a = 1 \text{ mm}; \quad y_m = \frac{m\lambda s}{na} = 2.946 \times 10^{-3} \text{ m}$$

$$(2): \quad n = 1.33; \quad y_m = \frac{m\lambda s}{na} = 2.215 \times 10^{-3} \text{ m}$$

**Example:**

Helium yellow light illuminates two slits, separated by 2.644 mm, in a Young's experimental set-up. If 21 bright fringes occupy 20 mm on a screen 4.5 m away, calculate the wavelength. Assume the refractive index of air is 1.

$$\Delta y = 20 / (21 - 1) = 1.00 \text{ mm}$$

$$\therefore \Delta y = \frac{\lambda s}{na} \quad \therefore \lambda = \frac{na\Delta y}{s} = 587.6 \text{ nm}$$

## Intensity Distribution:

In Young's experiment, the intensities of the two rays arriving at point  $P$  can be regarded as the same.  $I_1 = I_2 = I_0$ ,

$$I = 2I_0(1 + \cos \delta) = 4I_0 \cos^2 \frac{\delta}{2}$$

$$\delta = k(x_2 - x_1) + (\varepsilon_2 - \varepsilon_1) = k(x_2 - x_1) = ka \sin \theta = \frac{2n\pi}{\lambda} a \sin \theta$$

$$I = 4I_0 \cos^2 \left( \frac{n\pi a y}{s\lambda} \right)$$

## Fresnel Double mirror interferometer:

The two coherent secondary sources,  $S_1$  and  $S_2$ , are formed by reflections in the mirror. The arrangement is then identical to the Young's double-slit geometry with  $s=R+d$ ,  $a=2R\alpha$ .

## Fresnel's biprism:

The apical angle  $\alpha$  is about  $0.5^\circ$ . Light reaching the screen appears to come from the two coherent secondary sources  $S_1$  and  $S_2$ , formed by the biprism. The arrangement is then identical to the Young's double-slit geometry with  $s=R+d$ ,  $a=2R\delta=2R(n_g/n-1)\alpha$ .

## Lloyd's Mirror:

Lloyd's mirror provides a coherent secondary source  $S_1$  (formed by reflection from the mirror) from which light reaches the screen to interfere with light reaching the screen directly from  $S$ . A hidden phase change of  $\pi$  occurs upon reflection, and this corresponds to a  $\lambda/2$  path length change which must be included in calculations.

## Determination of the Central Bright Fringe:

When a **white** light is the source for the Young's double-slit experiment, the fringe width will be different for different wavelength, except for the central fringe which will appear white. All the other positions will exhibit a mixture of color. The central white fringe can be helpful to locate the position of the central fringe.

## Example:

A Fresnel double mirror is used with the source slit at 1 m from the mirror intersection A. When the screen is 4 m distant and  $\lambda = 500$  nm, the fringe width (separation) is 2 mm. Find the angle between the mirrors.

$$s \approx R + d; \quad a \approx 2R\alpha; \quad \Delta y = \frac{s\lambda}{na}; \quad \alpha = \frac{(R + d)\lambda}{2Rn\Delta y} = 6.25 \times 10^{-4} \text{ rad}$$

### Example:

Lloyd's mirror is used with sodium light ( $\lambda=589.3 \text{ nm}$ ) and the slit placed 3 mm above the reflecting surface and 3 m from the screen. Find the position of the first bright fringe above the level of the reflecting surface.

A dark fringe occurs at the level of the reflecting surface.

$$s = 3 \text{ m}; \quad a = 6 \text{ mm}; \quad \Delta y = \frac{s\lambda}{na} = 0.295 \text{ mm}$$

The first dark fringe is 0.295 mm above the level of the reflecting surface.

## Dielectric Thin Films:

The optical path difference for the first two emergent beams is,

$$\begin{aligned}
 OPD &= n_f (AB + BC) - n_0 AD = n_f \left( \frac{2t}{\cos i'} \right) - n_0 AC \sin i \\
 &= n_f \left( \frac{2t}{\cos i'} \right) - n_f \sin i' AC = n_f \left( \frac{2t}{\cos i'} \right) - n_f \sin i \\
 &= 2n_f t \left( \frac{1}{\cos i'} - \sin i' \tan i' \right)
 \end{aligned}$$

$$OPD = 2n_f t \cos i'$$

The conditions for constructive interference is  $2n_f t \cos i' + \lambda/2 = m\lambda$

The condition for destructive interference is  $2n_f t \cos i' + \lambda/2 = (m + 1/2)\lambda$

## Fringes of Equal Inclination:

They are formed by parallel incident beams from an extended source. Fringes of equal inclination are focused by a lens.

### Example:

Red light from a hydrogen discharge lamp,  $\lambda=656.28$  nm, is incident at  $30^\circ$  on a thin film of refractive index 1.5. What is the minimum thickness of film if an intensity maximum is to be observed?

$$2n_f t \cos i' + \lambda/2 = m\lambda$$

$$n \sin i = n' \sin i' \quad i' = 19.47^\circ$$

$$t_{\min} = \frac{\lambda/2}{2n_f \cos i'} = 1650 \text{ nm}$$

## Antireflection Coating:

Suppose now the film is on a substrate, if  $n_s > n_f > n_1$ , then both  $E_{1r}$  and  $E_{2r}$  will have a phase shift  $\pi$  at the interface due to the external reflection. For normal incidence, the condition (path condition) for destructive interference will be,

$$2n_f t = (m + 1/2)\lambda$$

$$t = (2m + 1) \frac{\lambda}{4n_f} \quad m = 0, 1, 2, \dots$$

amplitude condition:  $n_f = \sqrt{n_1 n_s}$

The minimum thickness single layer antireflection films are often referred to as **quarter-wavelength films**.

$$t_{\min} = \frac{\lambda}{4n_f} = \frac{\lambda_f}{4}$$

## Fringe of Equal Thickness:

Interference from a wedge-shaped dielectric film, producing localized fringes of equal thickness.

$$2n_f t + \Delta = \begin{cases} m\lambda & \text{bright fringes} \\ (m + 1/2)\lambda & \text{dark fringes} \end{cases}$$

For small wedge angle  $\alpha$ , the fringe width is,

$$\Delta x = x_{m+1} - x_m = \frac{t_{m+1} - t_m}{\alpha} = \frac{\lambda}{2n_f \alpha}$$

## Newton's Ring:

The Newton's ring is formed by an air wedge<sup>(a)</sup> between the spherical surface and an optically flat surface. Equal-thickness contours are concentric circles around the point of contact with the optical flat

$$R^2 = r_m^2 + (R - t_m)^2$$

$$R = \frac{r_m^2 + t_m^2}{2t_m}$$

For  $r_m \gg t_m$ ,  $r_m^2 = 2Rt_m$

The radius of the  $m$ th order of the dark fringe is

$$2n_f t + \Delta = \begin{cases} m\lambda \\ (m + 1/2)\lambda \end{cases}$$

$$r_m = \sqrt{\frac{m\lambda R}{n_f}}$$

## Example:

In an experiment the Newton's rings apparatus is illuminated with the green light from a mercury lamp,  $\lambda = 546.1 \text{ nm}$ . If the diameters of the 10th and 20th dark rings are 2.10 mm and 2.96 mm, respectively, calculate the radius of curvature of the convex surface. Assume  $n_f = 1$ .

$$r_m = \sqrt{\frac{m\lambda R}{n_f}}$$

$$R = 19.92 \text{ cm}$$

$$r_{20}^2 - r_{10}^2 = \frac{(20 - 10)\lambda R}{n_f}$$

## Michelson Interferometer:

$$2d \cos \theta_m = m\lambda \quad \Delta m = \frac{2\Delta d}{\lambda}$$

With increasing  $d$ , the fringe pattern appears to expand outward from the center, where they seem to originate. With decreasing  $d$ , the fringe pattern appears to shrink toward the center, where they seem to disappear.

## Coherence:

The OPD must not exceed the coherence length (the wave-train length) if interference is to occur. The Michelson interferometer can thus be used to determine the length of wave-train.

## Example:

Suppose a thin sheet of glass of refractive index  $n_s$  is inserted in one arm of a Michelson interferometer which is illuminated by mercury light,  $\lambda=546.1$  nm. If 94 fringes are displaced when the sheet is inserted, find its refractive index if the thickness is 0.0513 mm.

$$OPD = 2(n_s - 1)t = \Delta m \lambda$$

$$n_s = \frac{\Delta m \lambda}{2t} + 1 = \frac{94 \times 546.1 \times 10^{-9}}{2 \times 0.0513 \times 10^{-3}} + 1 = 1.5$$

## Film Thickness Measurement:

For normal incidence,  $2n_f t = m\lambda$

If the air-film thickness changes by  $\Delta t = d$ , the order of interference  $m$  changes accordingly,

$$2n_f \Delta t = 2n_f d = (\Delta m)\lambda$$

For a shift of fringes of magnitude  $a$ , the change in  $m$  is given by  $\Delta m = a/\Delta x$

$$d = \frac{a}{\Delta x} \frac{\lambda}{2n_f} = \frac{a}{\Delta x} \frac{\lambda_f}{2}$$

**Example:**

The figure shows the Jamin interferometer with two identical chambers placed in the paths of the interfering beams. The inner lengths of the chambers are 25 cm and a mercury source,  $\lambda=546.1$  nm, illuminates the system. If both chambers are evacuated and air is allowed to slowly fill one of them, the observer sees 133 fringes sweep by a cross-line hair in the focal plane of the telescope objective. Find the refractive index of the air in the chamber.

$$OPD = (n_{air} - 1)d = \Delta m \lambda$$

$$n_{air} = \frac{\Delta m \lambda}{d} + 1 = \frac{133 \times 546.1 \times 10^{-9}}{0.25} + 1 = 1.000291$$

**Example:**

A thin wedge of transparent liquid is formed between two flat glass plates. The spacers is a hair 0.1 mm in diameter placed 60 mm from the apex of the wedge and lying at the center of a dark fringe. If there are 462 dark fringes from the apex to the spacer, calculate the refractive index of the film when sodium light,  $\lambda=589.3$  nm, is used for the illumination.

$$\Delta x = x_{m+1} - x_m = \frac{t_{m+1} - t_m}{\alpha} = \frac{\lambda}{2n_f \alpha} = \frac{60 \times 10^{-3}}{462 - 1} = 0.13 \times 10^{-3} \text{ m}$$

$$\alpha = \frac{t_m}{x_m} = \frac{0.1}{60} = 1.667 \times 10^{-3}$$

$$n_f = \frac{\lambda}{2\Delta x \alpha} = 1.358$$

# Tugas

- Apa perbedaan interferensi dan difraksi? Jelaskan dengan gambar!
- Young's experiment with light point source (i.e.,  $\Delta s = 0$ ) produce two spectral lines  $\lambda_1 = 5770 \text{ \AA}$  and  $\lambda_2 = 5790 \text{ \AA}$ , Find:
  - Visibility of the interference fringes at observation plane.
  - Sketch the corresponding interference fringes.
